

Qno1: make a list of integer values and add 3. to each element in that list.

Input: [1,2,3,12,19,2]

Output: [4,5,6,15,22,5]

Try to make it in a function where it actually the list with 3 added to each item.

Qno2: Write to program to get the small value from a list.

Qno3: write a program where you basically make a tuple and append a single(Not possible in direct way)

Use the list function(list()) for conversion.

Qno4: type this into your program and check the output and explain why it is happening?

```
dict1 = {'name':'talha','password':'iamthebest','name':'John doe'}
```

type this dict1 into your code you can see there is another key with same name.

Question is: will this give an error? Or give us an output?

If it gives any output? Give reason
